# Price Discrimination with Experience Goods: Sorting-Induced Biases and Illusive Surplus 

Ron Goettler, Karen Clay<br>Carnegie Mellon University

Federal Reserve Bank of Boston July 25, 2006

## What we do

- Estimate a dynamic structural model of consumers'
- weekly usage of a nondurable experience good
- tariff choice from among a menu of three two-part tariffs
- Use household level data from an online grocer operating as a monopolist in a Midwest city.
- Simulate the estimated model under a variety of counterfactual pricing schemes.

## Why we do it

## Positive Objectives

- How much uncertainty do consumers have regarding the value of this new service?
- Do consumers have biased prior beliefs?
- How quickly is the uncertainty/bias resolved?
- Are preferences and learning rates related to demographics?

## Why we do it

## Positive Objectives

- How much uncertainty do consumers have regarding the value of this new service?
- Do consumers have biased prior beliefs?
- How quickly is the uncertainty/bias resolved?
- Are preferences and learning rates related to demographics?

## Normative Objectives

- How effective are two-part tariffs?
- What is the optimal menu of two-part tariffs?
- What is the effect of biases and switching costs on optimal tariffs and consumer surplus?

## Overview

## Results

- Consumers have sorting-induced biases:
- Those who choose tariffs with high (fixed, ex-ante) fees and low per-delivery prices tend to be overly optimistic.
- Beliefs can be biased conditional on tariff choice, even if consumers are correct on average.
- Consumers expect CS of $\$ 118$ but realize CS of $-\$ 45$.

## Results

- Consumers have sorting-induced biases:
- Those who choose tariffs with high (fixed, ex-ante) fees and low per-delivery prices tend to be overly optimistic.
- Beliefs can be biased conditional on tariff choice, even if consumers are correct on average.
- Consumers expect CS of $\$ 118$ but realize CS of $-\$ 45$.
- Consumers rarely switch tariffs: high switching costs (\$176)
- The optimal two-part tariff has a high fee and low per-delivery price, if switching costs always high.
- If switching costs are occasionally low, the optimal two-part tariff has a low fee and high per-delivery price.

## Results

- Consumers have sorting-induced biases:
- Those who choose tariffs with high (fixed, ex-ante) fees and low per-delivery prices tend to be overly optimistic.
- Beliefs can be biased conditional on tariff choice, even if consumers are correct on average.
- Consumers expect CS of $\$ 118$ but realize CS of $-\$ 45$.
- Consumers rarely switch tariffs: high switching costs (\$176)
- The optimal two-part tariff has a high fee and low per-delivery price, if switching costs always high.
- If switching costs are occasionally low, the optimal two-part tariff has a low fee and high per-delivery price.
- The gain in profits from offering a menu of tariffs is minimal.

## Online Grocer

## Ordering Details

## Ordering Online

- Initially connect direct via modem, then HTML
- Must know product names-no visual cues
- Delivery next day during a two-hour window Customer must be present
- Prices are the same as in partner chain
- Learn about service via print/radio advertising, mass mailings, news media, in-store advertising by partner chain, delivery truck displays, and word-of-mouth

## Tariff Choice

## Data

- 5310 households $(\mathrm{HH})$ enrolled $9 / 16 / 97$ to $1 / 23 / 99$
- Each HH chooses one of three tariffs (menu is fixed)
- 3 puzzles:
- HH could change at any time, but only change when quit
- $79 \%$ of HH on high fee plan have usage rates below the level needed to justify this plan
- Many HH on plans with fees never use the service

|  |  |  | plan | usage for | mean | never <br> Plan \# |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $F$ | $p$ | shares | min cost | usage | order |  |
| Plan 1 | $\$ 5.76$ | $\$ 0$ | .12 | $.67-1$ | .56 | .12 |
| Plan 2 | $\$ 1.14$ | $\$ 6.95$ | .32 | $.23-.67$ | .36 | .18 |
| Plan 3 | $\$ 0$ | $\$ 11.95$ | .56 | $0-.23$ | .20 | .57 |

## Demographic Characteristics, by Plan

| characteristic | Plan 1 | Plan 2 | Plan 3 |
| :--- | ---: | ---: | ---: |
| share all demographics missing | 27.3 | 33.5 | 66.5 |
| share no demographics missing | 8.9 | 5.6 | 2.4 |
| share income missing | 60.3 | 61.3 | 80.4 |
| share income > 90k | 38.2 | 30.7 | 23.2 |
| share income 50-90k | 45.2 | 42.4 | 49.2 |
| share income < 50k | 16.6 | 26.9 | 27.5 |
| mean \# adults | 2.1 | 2.0 | 2.0 |
| mean \# children | 1.9 | 1.4 | 1.3 |
| mean week enrolled | 24.0 | 23.2 | 21.3 |
| share female | 75.4 | 70.8 | 68.5 |
| share married | 89.5 | 79.4 | 76.1 |
| share co-habit | 3.1 | 5.9 | 5.5 |
| share single | 7.4 | 14.7 | 18.3 |

## Demographic Characteristics, by Plan

| characteristic | Plan 1 | Plan 2 | Plan 3 |
| :--- | ---: | ---: | ---: |
| share age 18-24 | 0.3 | 3.1 | 2.6 |
| share age 25-44 | 35.5 | 38.6 | 37.0 |
| share age 35-49 | 58.5 | 49.3 | 50.0 |
| share age 50-64 | 5.7 | 7.3 | 8.4 |
| share age 65+ | 0.0 | 1.7 | 2.0 |
| share some HS | 0.3 | 0.3 | 1.1 |
| share graduate HS | 6.6 | 10.1 | 10.8 |
| share some College | 19.7 | 25.0 | 31.2 |
| share graduate College | 49.6 | 43.1 | 36.7 |
| share some Grad School | 23.8 | 21.4 | 20.1 |

## Demographic Characteristics, by Plan

| characteristic | Plan 1 | Plan 2 | Plan 3 |
| :--- | ---: | ---: | ---: |
| share fulltime out | 66.8 | 70.2 | 72.0 |
| share parttime out | 14.5 | 10.5 | 11.0 |
| share fulltime in home | 14.5 | 13.5 | 10.6 |
| share student | 0.9 | 1.8 | 0.9 |
| share retired/other | 3.4 | 4.0 | 5.6 |
| share full out spouse | 89.0 | 87.5 | 86.9 |
| share part out spouse | 3.4 | 4.3 | 3.6 |
| share full home spouse | 3.7 | 4.1 | 2.6 |
| share student spouse | 0.6 | 0.8 | 1.9 |
| share retired/other spouse | 3.4 | 3.3 | 5.0 |

## Data

## Usage Rates

## Goettler, Clay Price Discrimination with Experience Goods

## A Bayesian Learning Model

- Each consumer (i.e., HH) is endowed with an unknown match-value, $\mu_{i}$, for the online grocer
- Each week, consumers decide whether to use online or traditional grocer
- If use online grocer, the realized utility provides unbiased signal of $\mu_{i}$, which is used to update beliefs
- At end of week consumers decide whether to change tariffs
- Consumers maximize expected discounted utility

## Utility

$\max _{\left\{s_{\tau}\left(l_{i \tau}\right), c_{\tau}\left(l_{i \tau}, s_{\tau}, u_{i \tau}\right)\right\}_{\tau=t}^{\infty}} \mathrm{E}\left[\sum_{\tau=t}^{\infty} \beta^{\tau-t}\left(\alpha F_{s_{\tau}}+\delta_{i \tau} \mathcal{I}\left(s_{\tau} \neq s_{\tau-1}\right)+U_{i c_{\tau} \tau}\left(s_{\tau}, u_{i \tau}\right)\right)| |_{i t}\right]$

- $c_{t} \in\{0,1\}$ is the consumer's usage choice in period $t$.
- $s_{t} \in\{1,2,3\}$ is the tariff choice.
- $u_{i 1 t}$ is i.i.d. shock, known by consumer, not econometrician.
- $F_{s_{t}}$ is the fixed fee of the selected tariff at beginning of $t$. traditional grocer: $\quad U_{i 0 t}=u_{i 0 t}$ online grocer: $\quad U_{i 1 t}=\mu_{i}+\epsilon_{i t}+\alpha p_{s_{i t}}+u_{i 1 t}$
- $p_{s_{i t}}$ is the per-use component of tariff $s_{i t}$.
- $\mu_{i t} \equiv \mu_{i}+\epsilon_{i t}$ is the experience signal.

## Bayesian Learning with Normal priors and signals

Signal Noise: $\epsilon_{i t} \sim$ i.i.d. $N\left(0, \sigma_{\epsilon}^{2}\right)$,
Initial Prior: $\quad \mu_{i} \sim N\left(m_{i 0}, \sigma_{i 0}^{2}\right)$
Posterior: $\quad \mu_{i} \sim N\left(m_{i t}, \sigma_{i t}^{2}\right)$, where

$$
\begin{aligned}
m_{i t} & =\frac{\sigma_{\epsilon}^{2} m_{i 0}+\sigma_{0}^{2} \mu_{i t}}{\sigma_{\epsilon}^{2}+\sigma_{0}^{2}} \\
\sigma_{i t}^{2} & =\frac{\sigma_{\epsilon}^{2} \sigma_{0}^{2}}{\sigma_{\epsilon}^{2}+\sigma_{0}^{2}}
\end{aligned}
$$

## Bellman Equation

$$
V_{u}\left(m_{i t}, \sigma_{i t}, s_{i t}, u_{i t}\right)=\max _{c_{i t}, s_{i t+1}} \mathrm{E}\left[U_{i c_{i t} t}+\beta V_{u}\left(m_{i t+1}, \sigma_{i t+1}, s_{i t+1}, u_{i t+1}\right) \mid\left(m_{i t}, \sigma_{i t}, s_{i t}, u_{i t}\right), c_{i t}\right]
$$

Following Rust (1987), assume $u$ is type I extreme value and integrate it out.

$$
\begin{gathered}
V\left(m_{i t}, \sigma_{i t}, s_{i t}\right)=\ln \left[\operatorname { e x p } \left(\beta \int \max _{s_{i t+1}}\left\{V\left(m_{i t}, \sigma_{i t}, s_{i t+1}\right)+\alpha F_{s_{i t+1}}+\delta_{i t} \mathcal{I}\left(s_{i t+1} \neq s_{i t}\right)\right\} G_{\delta}\left(d \delta_{i t}\right),\right.\right. \\
+\exp \left(m_{i t}+\alpha p_{s_{i t}}+\beta \int \max _{s_{i t+1}}\left\{V\left(m_{i t+1}, \sigma_{i t+1}, s_{i t+1}\right)+\alpha F_{s_{i t+1}}+\delta_{i t} \mathcal{I}\left(s_{i t+1} \neq s_{i t}\right)\right\}\right. \\
\left.\left.G_{\delta}\left(d \delta_{i t}\right) \Phi\left(d \mu_{i t} \mid m_{i t}, \sigma_{i t}\right)\right)\right]+ \text { Euler's constant }
\end{gathered}
$$

- $G_{\delta}$ is the iid distribution of switching costs.
- $\Phi$ is the perceived distribution of experience signals, which accounts for $\sigma_{\epsilon}$ and uncertainty about $\mu_{i}$ (via $\sigma_{i t}$ ).

## Solution and Implications

- Numerically solve using value function iteration, Hermite quadrature.
- Linear interpolation of $m_{i t}$. Fine grid for counterfactuals.
- Incentive to experiment increases in $\beta$ and $\sigma_{i t}$, decreases in $\sigma_{\epsilon}$.
- Consumers on high $F$ tariffs will tend to have high $m_{i t}$.
- This sorting is muted by switching costs, $\delta$.
- Higher consumption by consumers facing low $p$ due to low $p$ and sorting.

## Estimation

## Initial Beliefs

- Let $G_{\mu}\left(\mu_{i}\right)$ denote the distribution of match-values
- Rational Expectations assumes $G$ is known by the consumer
- Prior mean and variance is mean and variance of $G$
- Conditional on tariff choice, beliefs are unbiased.
- High usage by Plan 3 consumers is ok (information incentive).
- Persistently low usage by Plan 1 consumers not ok.
- Instead, we assume $G$ is not known by the consumer. Let $m_{i 0} \sim N\left(\mu_{i}, \sigma_{0}^{2}\right)$ denote the consumer's signal of $\mu_{i}$
- Prior for $\mu_{i}$ is $\mathrm{N}\left(m_{i 0}, \sigma_{0}^{2}\right)$
- On average, consumers have unbiased priors
- Conditional on tariff choice, however, beliefs are biased

## Estimation

## Initial Tariff Choice

- To address Puzzle \#3 (many HH choose tariff with fee and never use the service) we allow "ex-ante" mistakes in the initial tariff choice.

$$
\max _{0 \in\{1,2,3\}} \lambda_{s_{i 0}}+\Lambda\left(V\left(m_{i 0}, \sigma_{i 0}, s_{i 0}\right)+\alpha F_{s_{i 0}}\right)+\xi_{i, s_{i 0}},
$$

- The optimal initial tariff maximizes $V\left(m_{i 0}, \sigma_{i 0}, s_{i 0}\right)+\alpha F_{s_{i 0}}$.
- Alternative: consumers receive another signal after enrollment, before usage.

## Estimation

## Likelihood

$$
\begin{aligned}
L_{i}(\theta)=\int & {\left[\prod_{t=0}^{\tau_{i}} \operatorname{Pr}\left(s_{i t} \mid m_{i t}, \sigma_{i t}, s_{i t-1} ; \theta\right) \operatorname{Pr}\left(c_{i t} \mid m_{i t}, \sigma_{i t}, s_{i t} ; \theta\right)\right.} \\
& \left.\prod_{t=\tau_{i}+1}^{T_{i}} \sum_{s_{i t}} \operatorname{Pr}\left(s_{i t} \mid m_{i t}, \sigma_{i t}, s_{i t-1} ; \theta\right) \operatorname{Pr}\left(c_{i t} \mid m_{i t}, \sigma_{i t}, s_{i t} ; \theta\right)\right] \\
& \Phi\left(d\left\{m_{i}\right\}_{t=0}^{T_{i}} \mid \mu_{i} ; \theta\right) G_{\mu}\left(d \mu_{i}\right)
\end{aligned}
$$

- $\Phi\left(d\left\{m_{i}\right\}_{t=0}^{T_{i}} \mid \mu_{i} ; \theta\right)$ integrates over the entire sequence of beliefs conditional on the match value
- $G_{\mu}\left(d \mu_{i}\right)$ integrates over the match value
- After the last usage in week $\tau_{i}$ the tariff choice is censored
- $s_{i t}$ is deterministic (i.e., 0 or 1 ) given beliefs and $s_{i t-1}$
$-\operatorname{Pr}\left(c_{i t}\right)$ is logit (Miller, 1984, Rust, 1987)

## Estimation

## Random Coefficients via Importance Sampling

$$
L_{i}(\rho)=\int L_{i}\left(\theta_{i}\right) g\left(\theta_{i} \mid \rho\right) d \theta_{i}=\int L_{i}\left(\theta_{i}\right) \frac{g\left(\theta_{i} \mid \rho\right)}{h\left(\theta_{i}\right)} h\left(\theta_{i}\right) d \theta_{i}
$$

- $g(\theta \mid \rho)$ is density of random coefficients, parameterized by $\rho$
- Draw $\left(\theta_{i}^{1}, \ldots, \theta_{i}^{N S}\right)$ from $h$ (based on no RC estimates)
- Compute $L_{i}\left(\theta_{i}^{n s}\right)$ once and choose $\rho$ to maximize

$$
\tilde{L}_{i}^{N S}(\rho)=\frac{1}{N S} \sum_{n s=1}^{N S} L_{i}\left(\theta_{i}^{n s}\right) \frac{g\left(\theta_{i}^{n s} \mid \rho\right)}{h\left(\theta_{i}^{\theta s}\right)}
$$

- See Ackerberg (2002) for details

## Pricing Counterfactuals

Two goals:

- Isolate the effects on consumer behavior and revenues of
- ex-ante tariff choice mistakes
- switching costs
- match-value uncertainty
- Investigate optimal monopolist pricing:
- Ex-ante versus ex-post pricing
- Price discrimination via menus to screen consumers

Values generated by simulating 5000 consumers over 100 weeks for each of 100 draws of $\theta$.

- Minimal ability to screen consumers to increase revenues

## Pricing Counterfactuals

## Tariffs and Revenues as Initial Uncertainty varies

Pricing Counterfactuals

## Tariffs and Revenues as Switching Costs vary

## Conclusion

- Peapod serves 250,000 customers and offers a per-use price of \$6.95.
- A puzzle: what demand systems would yield a substantial gain for using menus to segment consumers?

[^0]:    All revenue and surplus values are in dollars per consumer.
    Weekly $\beta_{\text {firm }}=.998$. Hence, one dollar per week has present value of $\$ 500$.
