Monthly Stock Market Report

This document is for internal use only. The document or any of its contents should not be distributed outside of the Federal Reserve System without permission.

Market Analysis for Period Ending Monday, December 1, 2003

This document presents technical and fundamental analysis commonly used by investment professionals to interpret direction and valuation of equity markets, as well as tools commonly used by economists to determine the health of financial markets and their impact on the domestic United States economy. The purpose is to provide a synopsis of equity markets from as many disciplines as possible, but is in no way an endorsement of any one mode of study or source of advice on which one should base investment decisions.

Definitions of terms and explanations of indicator interpretation follow the charts in the Endnotes section.

Technical Trends

Figure 1 presents price trends and daily volumes for the New York Stock Exchange and Nasdaq Composite Indices.

The New York Stock Exchange Composite Index (NYSE Index) closed Monday, December 1 at 6147.35. The index is at its highest level since May 2002. Since hitting its low on March 12, the NYSE has risen 37.0 percent, and is up 22.9 percent for the year.

The National Association of Securities Dealers Composite Index (Nasdaq Index) closed at 1989.82, its highest level since January 2002. Since the opening of the Iraq conflict the Nasdaq has risen 56.5 percent and is up 49.0 percent year-to-date. (figure 1).

Figures 2, 3, and 4 present some technical indicators commonly cited by stock market analysts.

The current technicals seem to indicate that there may not be much more room for growth in the markets. The relative strength index for the NYSE Composite had a value of 69.9 percent as of October 20, right at the border of overbought territory (figure 2, upper panel). The number of stocks making new 52-week highs has remained high, while new lows are almost zero (figure 3, upper panel). The middle panel shows that momentum (overbought/oversold oscillator) is in overbought territory and climbing recently, a potentially bearish indicator. The Market Breadth indicator (figure 3, bottom

panel) has followed the Index pretty closely, signaling that the 2003 boom has been fairly widespread.

For the Nasdaq Index, the relative strength index is in neutral territory but rising towards overbought (figure 2). The upper panel of figure 4 shows the number of new highs is still far above the number of new lows. Advancing stocks have slightly outnumbered declining ones since September (lowest panel, figure 4). The momentum indicator has just crossed into overbought territory and continues to rise, a bearish indicator (figure 4, middle panel).

Volatility

Indicators of market volatility are shown in figure 5.

The Chicago Board of Options Exchange (CBOE) provides daily measures of volatility for the S&P 100 (VIX) and for the Nasdaq 100 (VXN). Both volatility indicators dropped sharply in the spring and remain low; the VIX is still near its lowest point since August 2002, while the VXN was last this low in December 1998.

Put/Call ratios appear in figure 6.

Monthly data are shown from January 1997 through November 2003. The CBOE individual equity put/call ratio was unchanged and remains in bullish territory. The S&P 100 put/call ratio decreased and is in neutral territory.

Sector Performance

Figure 7 compares the performance of the various economic sectors within the S&P 500 as well as other international and style indices.

Nine of the ten economic sectors in the S&P 500 have a positive year-to-date return as of December 1. The information technology and consumer cyclicals sectors have been the strongest sectors in 2003, rising 44.6 and 32.2 percent respectively. The telecommunications sector, which had the largest loss in the last five years, continues to lag far behind the field, with a loss of 4.8 percent in 2003 (figure 7, top panel).

The Wilshire 5000, composed of all U.S. equity issues, is now up 25.5 percent year-to-date. The German DAX has enjoyed 2003 even more, rising 32.1 percent, while Japan's Nikkei 225 (21.3 percent) has kept the pace. The U.K's FTSE 100 has not had the same level of success, but is still up 11.9 percent for the year (figure 7, middle panel).

Each of the Russell style indices has increased more than twenty percent in 2003. The Russell 2000 Small-Cap Index has seen the biggest increase this year by far, almost 45 percent, after experiencing negative returns on average over the last five years (figure 7, bottom panel).

Valuation

Figure 8 displays historical and current price-earnings ratios for the S&P 500 economic sector groups described above in the top panel, and analyzes earnings growth in 5-year, 3-year, and 1-year increments for each sector in the bottom two panels. Figure 9 graphs the current and previous earnings forecasts for several calendar years in the top panel, and lists the current and previous growth of earnings forecasts for each S&P 500 sector in the two tables. Figure 10 shows three measures of historical and future valuation: historical PE ratios in the top panel, forward and trailing PE ratios using analysts' estimates of operating earnings in the middle panel, and strategists' two-year forecasts of earnings growth in the lower panel.

Recent increases in prices have caused price-earnings ratios to increase for most S&P 500 economic sectors. Due to negligible earnings, the consumer cyclical sector has unreliable PE ratios. Otherwise, the materials and utilities sectors have risen the most since the fourth quarter of 2002, to 63.6 and 36.5, respectively. The PE for the energy sector has been cut in half and then some, from 39.5 to 16.2, due to declines in stock prices and strengthened earnings (figure 8, top panel).

The analysts surveyed by Thomson Financial/First Call expect a 22.4 percent increase in earnings for the S&P 500 in the fourth quarter of 2003, and an 18.5 percent increase for calendar year 2003. In the fourth quarter, the growth of earnings is expected to be greatest for the materials and financial sectors, while earnings for the telecom sector are expected to fall the most. Thomson warns, however, that the strong performance of the financial sector is reliant on a big increase from last year's fourth quarter, when investment banks took charges to reflect the fines assessed by the New York Attorney General's office. Still, the rate of negative earnings pre-announcements is far below those of the last few years, and the growth in earnings should be strong (figure 9).

The macro projections from strategists for the growth of earnings for the Standard and Poor's 500 index over the next two years have been revised downward to 13.4 percent in the third quarter of 2003. The **S&P 500 trailing price-earnings ratio** decreased to 26.4 from 28.2. During the third quarter, the price-earnings ratio for the Russell 2000 index increased to 30.6 from 26.8. The 2003 fourth quarter forecast for the **S&P 500 forward price-to-operating-earnings ratio**, using bottom-up forecasts

from analysts, increased to 17.7 from 17.1 in the third quarter (figure 10).

Breadth of the S&P 500

Prices rose from a year ago for 84.8 percent of stocks in the S&P 500 in the third quarter of 2003, up from 43.8 percent in the second quarter and 26.3 for calendar year 2002 (figure 11, middle panel). Although the median price-to-operating-earnings ratio stayed roughly the same for all deciles of the S&P 500, only four deciles have median ratios below the historical average price-to-earnings ratio of 14.4 (figure 11, bottom).

Comparative Returns

The dividend-price ratio, an indication of the yield investors receive through dividends by holding stocks, decreased to 1.66 percent in the third quarter from 1.72 percent in the second quarter. The earnings-price ratio increased to 3.86 percent in the third quarter from 3.68 percent in the second quarter. Both of these ratios are still substantially below the 4.64 percent real rate of interest on corporate bonds and their respective historical averages, 2.90 percent and 5.97 percent (figure 12). Typically, the earnings-price ratio falls below the real return on bonds when analysts expect earnings to rise rapidly.

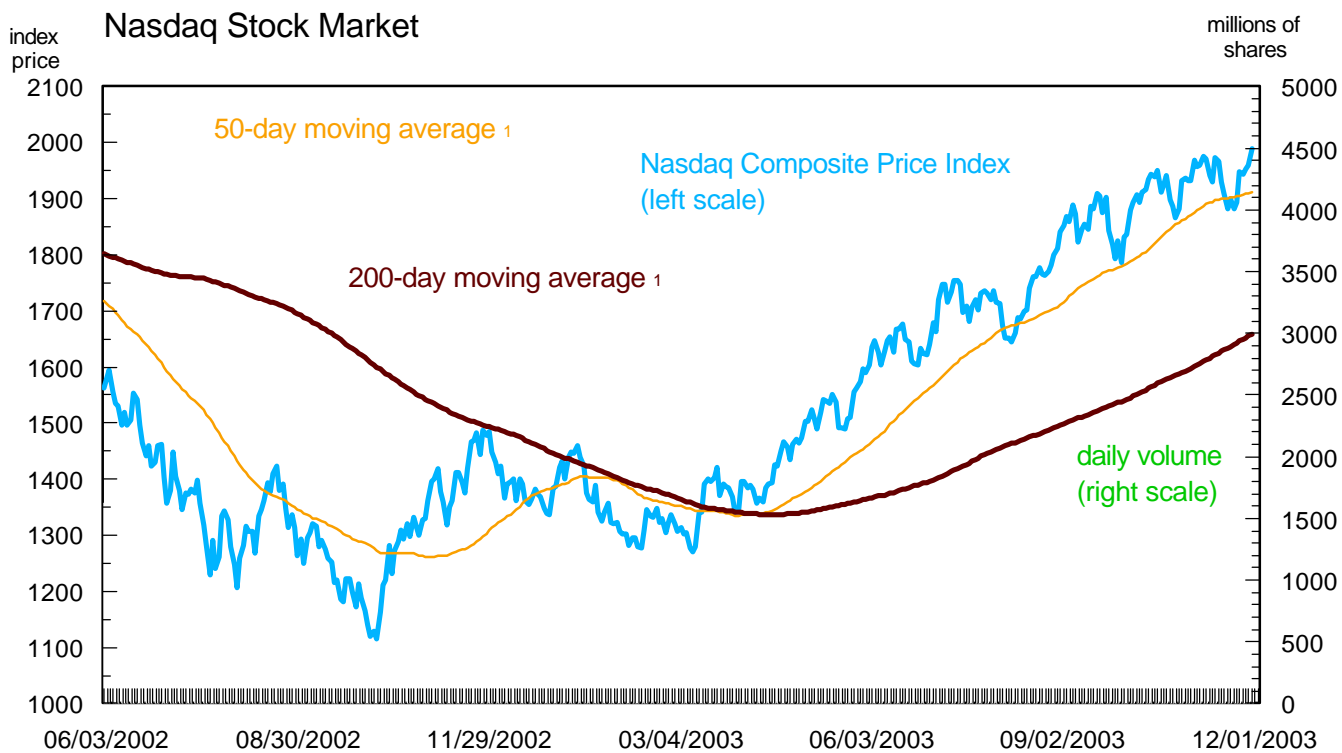

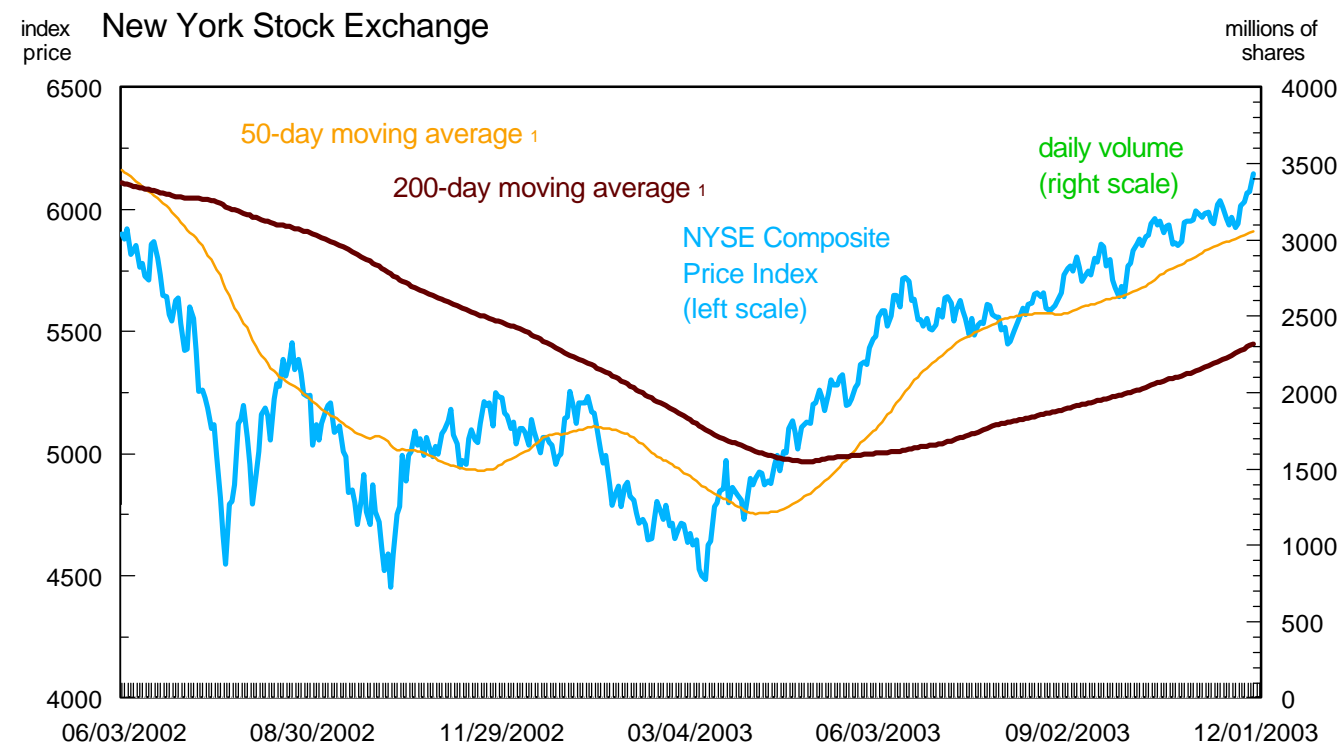

As earnings have begun to recover, the operating profit payout rate for nonfinancial corporations has declined, from 54.7 in the second quarter to 46.8 in the third quarter (figure 13, lower panel). It remains to be seen if the elimination of the dividend tax will have any effect on the payout rate.

Moody's downgraded more of both investment grade and speculative grade securities in October than September, while the upgrades stayed relatively constant (figure 15, top and middle panels). The default rate on junk bonds decreased slightly in October to its lowest point since January 2001 (figure 15, lower panel).

Endnotes

1. 50-Day, 200-Day Moving Average: Moving averages represent the average price investors paid for securities over a historical period, and present a smoothed picture of the price trends, eliminating the volatile daily movement. Because these lines offer a historical consensus entry point, chartists look to moving average trend lines of index prices to define levels of support or resistance in the market. When a chart trend is predominantly sideways (Figure 1, top chart), moving averages and the underlying series frequently cross, but during a time of prolonged increase or decrease (bottom chart) the daily prices of a security typically are above or below the trailing average. Moving above or below the 50-day moving average is sometimes associated with rallies or corrections. Similarly, prolonged movements, such as bull and bear markets can be represented by securities remaining above or below their 200-day moving average for prolonged periods of time.
2. 9-Day, 18-Day Moving Averages: The 9-day and 18-day moving averages are often used together to provide buy and sell signals. Buy signals are indicated by the 9-day average crossing above the 18-day when both are in an uptrend. The reverse, the 9-day crossing below the 18-day while both moving averages are declining is a sign to sell. However, this simple can often be misleading because of its dependence on trending markets and inability to capture quick market turns.
3. Relative Strength Index: This (RSI) momentum oscillator measures the velocity of directional price movements. When prices move rapidly upward they may indicate an overbought condition, generally assumed to occur above 70 percent. Oversold conditions arise when prices drop quickly producing RSI readings below 30 percent.
4. New Highs, New Lows: A straightforward breadth indicator, this is the 10-day moving average of the number of stocks on a given index or exchange making new 52-week highs or lows each day. This indicator also demonstrates divergence. If an index makes a new low, but the number of stocks in the index making new lows declines, there is positive divergence, and in this case a lack of downside conviction. Conversely, In rising markets if an index makes a new high but the number of individual stocks in that index making new highs does not increase this suggests a false rally.
5. Overbought / Oversold Oscillator: This momentum indicator is calculated by taking the 10-day moving average of the difference between the number of advancing and declining issues for a given index. The goal of the indicator is to show whether an index is gaining or losing momentum, so the size of the moves are more important than the level of the current reading. This is first affected by how the oscillator changes each day, by dropping a value ten days ago, and adding one today. If the advance decline line read minus 300 ten days ago, and minus 100 today, even though the market is down again, the oscillator will rise by 200 because of the net difference of the exchanged days' values. This suggests a

trough, however, if today's reading was minus 500 it would demonstrate a gain in downside momentum.

The magnitude in moves is useful when compared with divergence to the index price. If the Dow peaks at the same time the oscillator peaks in overbought territory, it suggests a top. If the index then makes a new high but the oscillator fails to make a higher high, divergence is negative and momentum is declining. If the index at this point declines and the oscillator moves into oversold territory it may again be time to buy. If the index rises but does not make new highs, but the oscillator continues to rise above a previous overbought level, upside momentum exists to continue the rally.

6. Cumulative Advance / Decline Line: Referred to as market breadth, the indicator is the cumulative total of advancing minus declining issues each day. When the line makes new highs a rally is considered widespread, but when lagging a rally is seen as narrow.
7. Volatility: With regard to stock prices and stock index levels, volatility is a measure of changes in price expressed in percentage terms without regard to direction. This means that a rise from 200 to 202 in one index is equal in volatility terms to a rise from 100 to 101 in another index, because both changes are 1 percent. Also, a 1 percent price rise is equal in volatility terms to a 1 percent price decline. While volatility simply means movement, there are four ways to describe this movement:
 1. *Historic volatility* is a measure of actual price changes during a specific time period in the past. Mathematically, historic volatility is the annualized standard deviation of daily returns during a specific period. CBOE provides 30 day historical volatility data for obtainable stocks in the Trader's Tools section of this Web site.
 2. *Future volatility* means the annualized standard deviation of daily returns during some future period, typically between now and an option expiration. And it is future volatility that option pricing formulas need as an input in order to calculate the theoretical value of an option. Unfortunately, future volatility is only known when it has become historic volatility. Consequently, the volatility numbers used in option pricing formulas are only estimates of future volatility. This might be a shock to those who place their faith in theoretical values, because it raises a question about those values. Theoretical values are only estimates, and as with any estimate, they must be interpreted carefully.
 3. *Expected volatility* is a trader's forecast of volatility used in an option pricing formula to estimate the theoretical value of an option. Many option traders study market conditions and historical price action to forecast volatility. Since forecasts vary, there is no specific number that everyone can agree on for expected volatility.
 4. *Implied volatility* is the volatility percentage that explains the current market price of an option; it is the common denominator of option prices. Just as p/e ratios allow comparisons of stock prices over a range of variables such as total

earnings and number of shares outstanding, implied volatility enables comparison of options on different underlying instruments and comparison of the same option at different times. Theoretical value of an option is a statistical concept, and traders should focus on relative value, not absolute value. The terms "overvalued" and "undervalued" describe a relationship between implied volatility and expected volatility. Two traders could differ in their opinion of the relative value of the same option if they have different market forecasts and trading styles.

8. CBOE Volatility Index (VIX): The VIX, introduced by CBOE in 1993, measures the Volatility of the U.S. equity market. It provides investors with up-to-the-minute market estimates of expected volatility by using real-time OEX index option bid/ask quotes. This index is calculated by taking a weighted average of the implied volatilities of eight OEX calls and puts. The chosen options have an average time to maturity of 30 days. Consequently, the VIX is intended to indicate the implied volatility of 30-day index options. It is used by some traders as a general indication of index option implied volatility. (Source: CBOE)
9. CBOE NASDAQ Volatility Index (VXN): Like the VIX, the VXN measures implied volatility, but in this case for NASDAQ 100 (NDX) index options, thereby representing an intraday implied volatility of a hypothetical at-the-money NDX option with thirty calendar days to expiration. Both the VXN and the VIX are used as sentiment indicators for the NASDAQ 100 and for the broader market, respectively. Higher readings and spikes generally occur during times of investor panic and at times coincide with market bottoms. Low readings suggest complacency and often occur around tops in index prices.
10. Put / Call Ratio: These ratios are used as contrary sentiment indicators. Higher ratio values, indicating more put trading, is considered more bullish. The CBOE index ratio tracks trade volume of all exchange traded index options, reflecting sentiment of professional and institutional strategies. The CBOE equity ratio is composed of trade volume for individual equity options and a better indicator of retail investor sentiment. Equity ratio readings 60/100 and 30/100 denote levels of bullishness and bearishness. Similarly, bullish and bearish boundaries for the S&P 100 are 125/100 and 75/100.
11. 2-Year Growth of Earnings: Growth of earnings over subsequent 8 quarters. Current observations use forecast of earnings from macro projections.
12. Earnings and Dividend Price Ratios: These ratios represent an investor's yield from earnings and dividend payments. Historically, the EP ratio often has exceeded the real return on bonds, reflecting the greater risk to shareholders for choosing equity investments. Recently, the EP ratio has fallen below the return on bonds as investors demand uncharacteristically large capital gains to compensate for the low earnings yield. Historically, the EP ratio has fallen below the real bond rate only when earnings are expected to rise dramatically.

13. Real Bond Rate: Moody's composite yield of A-rated corporate bonds less the expected rate of inflation over the next 10 years as measured by the consumer price index from the Survey of Professional Forecasters, published by the Federal Reserve Bank of Philadelphia.
14. Moody's Ratings: Denotes the change in dollar amount of investment grade (above BA1) or speculative grade (BA1 or below) securities outstanding for a particular company if that company is up/downgraded during a given month. For example, if company XYZ was upgraded, and they had bonds rated AA2 for \$10, AA1 for \$2, and A3 for \$15, this company's contribution to the chart value is \$27.
15. Investor Expectations: Internally generated composite of the Conference Board's 12-month forward investor expectations for no change, increase, and decrease in the stock market. Composite values of 50 indicate neutral expectations. Values below 50 demonstrate bearish sentiment, though the chart demonstrates that the outlook of investors is typically bullish.
16. Tobin's q: The ratio of the market value of equity plus net interest bearing debt to current value of land, inventories, equipment, and structures.
