[Appendix]
• Application criteria for the IMA formula …37
Proposal for an IMA formula
Under the Standardised Approach

• Required capital for the bank
  \[= \sum \text{Required capital amounts for all the business lines}\]
  
  \[\Rightarrow\] Required capital for each business line
  \[= [\beta \text{ determined by the regulators}] \times [\text{Exposure Indicator (EI)}]\]

• “Working Paper (September 2001)”
  \[\Rightarrow\] EI \(\Rightarrow\) Gross Income (GI)

• Required capital for the bank
  \[= \sum \{\text{Required capital for business lines} = \beta \times GI \quad (1-1)\} \]
Standardised Approach (2)

{Structure}
- The level and size of the activity in each business line are reflected in GI.
- The risk characteristic of each business line is reflected in β.

{Limitations}
- The result is not directly linked to the loss data.
- The difference in profile of operational risk between event types within the same business line is not reflected.
Advanced Measurement Approaches [AMA] (1)

{Structure}
Under the AMA

• Each bank measures the required capital
  – based on its own loss data;
  – with its own measurement method;
  – using the holding period and confidence interval determined by the regulators.

• WP refers to
  – Loss Distribution Approach (LDA)
  – Internal Measurement Approach (IMA)
  – Scorecard Approach
Advanced Measurement Approaches [AMA] (2)

{Limitations of Standardised Approach}
- The result is not directly linked to the loss data.
- The difference in profile of operational risk between event types within the same business line is not reflected.

{Features of the AMA}
- Based on the collection of loss data.
- “Low-frequency / high-severity” for each event type in addition to business line to be reflected.

✧ **Backtesting**
  To be verified through backtesting based on historical loss data.

✧ **Floor**
  Initially set at 75% of the Standardised Approach.
Advanced Measurement Approaches [AMA] (3)

Hold loss data? 
Yes → Each bank backtests its method based on loss data? Yes → AMA
IMA
LDA
Scorecard approach
...
Floor imposed

No → Standardised approach

<Features>
1. Based on the loss data.
2. Reflects the risk profile of each event type / business line (low-frequency, high-severity).

<Limitations>
1. Not directly linked to loss.
2. Risk profile of each event type / business line not reflected.

Banks can choose between methods under the AMA and the Standardised Approach depending on the characteristics of the business line concerned.
Proposal for an IMA formula (1)

• Proposal for an explicit formula for the IMA, one alternative under the AMA
  – Required capital is determined for each combination of business line / event type.
    • Required Capital = \( \gamma \times EL \)
      ➢ EL = Average annual loss amount
        => Derived from the bank’s own internal loss data
Proposal for an IMA formula (2)

“Low-frequency / high-severity” is reflected through

- An adjustment factor \((1+A/\sqrt{n})\) incorporated as follows.
  - Required Capital = \(\lambda \times EL \times (1+A/\sqrt{n})\) --- (1-2)

\(\lambda\) = Constant determined for each business line based on the holding period and confidence interval specified by the regulators.

\(A\) = Constant for each business line / event type combination

\(n\) = Number of events.
IMA Foundation Model

◆ Parameters $A$ and $\lambda$;
  - Estimated by each bank based on its own internal data.
  - “Generic Model”

  ➢ Could also be uniformly determined by the regulators based on the global data.
  - “Foundation Model”
Floor for AMA

✧ A floor is imposed on AMA because;

- The internal methods are still in early stages of implementation.
- AMA still lacks detailed criteria for specific quantification methods.

✧ The effect of such factors varies between different methods. The regulators should examine the degree of such an effect to determine the level of the floor accordingly.
Floor for IMA Foundation Model

✧ All the parameters are fixed under the IMA Foundation Model.

✧ The stage of implementation does not matter as verification of methods employed by individual banks is not required.

• Detailed criteria for quantification methods are uniformly established.

✧ If IMA in a rigorous form is developed, it should be able to enjoy a floor set at a lower level in light of the very reasons for imposition of the floor articulated in the WP. Eventually, such a floor could be dropped.
Banks can choose between methods under the AMA and the Standardised Approach depending on the characteristics of the business line concerned.

IMA Foundation Model
(Summary)

- **Hold loss data?**
  - Yes: Each bank backtests its method based on loss data?
    - Yes: AMA
      - IMA
        - LDA
        - Scorecard approach
      - Floor imposed
    - No: IMA Foundation Model
      - Parameters determined by the regulators to ensure consistency
      - Floor can be set at a lower level
  - No: Standardised approach

**<Features>**
1. Based on the loss data.
2. Reflects the risk profile of each event type / business line (low-frequency, high-severity).

**<Limitations>**
1. Not directly linked to loss.
2. Risk profile of each event type / business line not reflected.
[2]

Relationship with the basic structure proposed in Consultative Paper 2
Relationship between formulae

• Basel Committee proposed the following structure of the IMA formula in CP2 (January 2001).
  > Required Capital (CP2) = \( \lambda \times EI \times PE \times LGE \times RPI \)

• The IMA Formula (1-2) proposed in this presentation can be related to this basic structure as follows.
  > Required Capital = \( \lambda \times EL \times (1 + A/ \sqrt{n}) \) --- (1-2)

<table>
<thead>
<tr>
<th>EI</th>
<th>PE</th>
<th>LGE</th>
<th>RPI</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL</td>
<td></td>
<td></td>
<td>1 + A/ \sqrt{n}</td>
</tr>
</tbody>
</table>
The issues raised as to actual implementation of: “Required Capital = \( \lambda \times EI \times PE \times LGE \times RPI \)” proposed in CP2.

- In the case where the size of the bank’s business operation is changed due to merger/demmerger on a large scale or acquisition/divestiture of important new businesses, the bank can modify the internal loss data based on the EI (scaling adjustment).

- The following issues, however, would be raised.
  - Definition of EI can be difficult depending on the event type.
  - Even if such a definition is possible, it is difficult to actually collect data on the EI. The calculation of PE is therefore difficult.
EL (2)

◆ When total transaction amount (= Nµ) is selected as EI;
  ➢ actual calculation of EI * PE * LGE shows that EI and PE cancel out each other.
  ➢ the result equals the annual loss amount.

EI * PE * LGE = Nµ * n/N * µL/µ = n µL = EL (annual loss amount)

N: Total number of transactions, µ: Average transaction amount,
n: Number of events, µL : Average of loss amount

✧ Formula (1-2) enables calculation of required capital without directly measuring EI and PE. by incorporating EL.
\[ \lambda \]

- A factor related to the required capital / EL ratio.
- A constant determined for each business line by the confidence interval and the holding period.
\[ 1 + \frac{A}{\sqrt{n}} \] (1)

- RPI reflects the “low-frequency / high-severity”
  can be divided into;
  - Adjustment factor for frequency
    - Incorporates the profile of each bank as to the level of low-frequency.
    - Required capital / EL becomes greater when \( n \) becomes smaller.
    - This feature can be reflected in the IMA formula by introducing a non-linear factor \( \frac{1}{\sqrt{n}} \).
    - Easily calculated based on internal data.
\[
1 + A \sqrt{n} \quad (2)
\]

- Adjustment factor for severity
  - The greater the dispersion of the loss distribution (mean \( \mu_L \); standard deviation \( \sigma_L \)), the greater becomes the adjustment factor for severity.
  - Incorporates the profile of each bank as to the level of high-severity.
  - Determined for each business line / event type combination as a constant A.
The profile of loss distribution varies between business line / event type combinations.

This difference is explained by the difference between business line / event type combinations.

By establishing $A$ for each business line / event type combination, therefore, it is possible to reflect different characteristics of different loss distribution in the formula.
Common determination of $A$ and $\lambda$ based on the global data

- $A$ and $\lambda$ can be different between banks.

- We propose the Foundation Model for which;
  - $A$ and $\lambda$ are determined by the regulators based on the global data.
    - $\lambda$ depends mainly on business line, and
    - $A$ on business line / event type combination.
Characteristics of the IMA formula (1-2)

- Based on the linear formula $EI \times PE \times LGE (= EL)$.
- Non-linearity is incorporated through multiplication by the inverse of the square root of the number of events.
- The level of severity is differentiated between event types.
- Exposure Indicator is not explicitly shown.
- Furthermore, under the Foundation Model:
  - The parameters $A$ and $\lambda$ can be commonly determined on a global basis.
  - No necessity for model validation for each bank in the actual implementation.

Possible to set the floor at a lower level than for other methods under the AMA.
Determination of the parameters for the IMA formula
Method for calibration (1)

In the IMA formula (1-2), Required capital is expressed as:

\[ \lambda * EL * (1+A/\sqrt{n}) \]

where the following observations are made.

- \(\lambda\) for each business line.
- \(A\) for each combination of business line / event type.
- \(EL\) and \(n\) for each combination of business line / event type.

Accordingly, the required capital for each combination of business line / event type is measured with the IMA formula as follows.

\[ \lambda_j * EL_{ij} * (1+A_{ij}/\sqrt{n_{ij}}) \quad (i: \text{Event type}, j: \text{Business line}) \]

(Note) This presentation demonstrates that the above formula with \(A\) and \(\lambda\) calibrated inductively gives the required capital amount. A theoretical demonstration is also possible given a certain distribution.
As IMA is an alternative under the AMA, the required capital for each combination of business line / event type is the unexpected loss (the tail of the distribution) with the holding period and confidence interval specified by the regulators. (Expressed as $UL_{ij}$). $U_{ij}$ is determined either on the basis of actual distribution or theoretically.

Calibrating IMA formula

Approximating the UL with IMA.

$UL_{ij}$

$IMA_{ij} = \lambda_j \times EL_{ij} \times (1 + A_{ij} / \sqrt{n_{ij}})$

Determine constants $\lambda$ and $A$ (regression analysis)

Calibration of the Foundation Model demonstrated later. Common $\lambda$ and $A$ for all the banks determined based on the global data (consecutive QIS etc.).
Method for calibration (3)

Business Line $j$

Unexpected loss with the holding period and confidence interval specified by the regulators: $UL_{ij}$

Required capital measured with IMA: $IMA_{ij}$

$$UL_{ij} = \lambda_j \times EL_{ij} \times (1 + \frac{A_{ij}}{\sqrt{n_{ij}}})$$

Parameters $\lambda_j$ and $A_{ij}$ are determined so that they can be common to all the banks and event

---

Event type 1

- $UL_{1j}$
- $IMA_{1j}$
- $EL_{1j}$
- $A_{1j}$
- $\sqrt{n_{1j}}$

Event type 2

- $UL_{2j}$
- $IMA_{2j}$

UL/EL = 93.2

- Required capital under Standardised Approach
  - \( = 200,000 \times 20\% = \text{JPY 40,000 million} \)
Bank as a whole

◆ If the bank has only two business lines shown above, i.e. commercial banking and trading & sales, the required capital for the bank as a whole is the sum of the above.

◆ Required capital under the IMA
  \[ = 182,501 + 8,914 = \text{JPY 191,415 million} \]

◆ Required capital under Standardised Approach
  \[ = 180,000 + 40,000 = \text{JPY 220,000 million} \]
Banks can choose between methods under the AMA and the Standardised Approach depending on the characteristics of the business line concerned.

**Conclusion**

**Hold loss data?**
- Yes: Each bank backtests its method based on loss data?
  - Yes: AMA
    - IMA
    - LDA
    - Scorecard approach
  - No: IMA Foundation Model
    - Floor imposed
    - Parameters determined by the regulators to ensure consistency
    - Floor can be set at a lower level

**AMA**
- 1. Based on the loss data.
- 2. Reflects the risk profile of each event type / business line (low-frequency, high-severity).

**Standardised approach**
- 1. Not directly linked to loss.
- 2. Risk profile of each event type / business line not reflected.

**<Features>**
- $\lambda \cdot \text{EL} \cdot (1 + A/\sqrt{n})$: $\lambda$ and $A$ can be calibrated based on the global data. e.g. $\lambda=19.46$, $A=15.31$.
[Appendix]

Application criteria for the IMA formula
Sufficiency of EL (1)

• The IMA formula (1-2) is based on EL.
  ➢ It is crucial that the observed amount of EL is sufficiently large.

  – When the observed EL is large enough, the Formula (1-2) can be applied as it is.
  – If not, the reliability of the calculation with this formula in its original form might be low.
Sufficiency of EL (2)

Two cases where EL is not adequate depending on the size of EI.

Observed EL is deemed insufficient when;

- EI is small. [Case 2-1]
  ✷ No event causing EL has occurred because the number of transactions in the past is very small.
- EI is large. [Case 2-2]
  ✷ The frequency of events is limited to a very low level due to the high control capabilities etc. although the number of transactions is reasonably large.
Two cases correspond to

- The second quadrant [Case 2-2]
- The third quadrant [Case 2-1]

among the three types of combinations of the size of EL and EI.
Sufficiency of EL (4)

- In Cases 2-1 and 2-2, EL is not significant.
  - The required capital amount calculated using the IMA formula (1-2) is not very reliable.
  - In order to ensure that the measurement is conservative, a floor is established for the IMA formula (1-2).
Sufficiency of EL (5)

◆ Steps towards required capital calculation:

[Step 1]

“Collect internal data”
– Banks collect internal data on loss and exposure indicators.

[Step 2]

“Check the significance / meaningfulness of the collected data”
– using the exposure indicator concerned.
Sufficiency of EL (6)

– [Case 1] The observed EL is sufficient.

   If the data collected proves statistically significant, the bank can calculate the capital charge using only the loss data.
   ✷ Formula (1-2): Required Capital = $\lambda \times EL \times (1 + A/\sqrt{n})$

– [Case 2] The observed EL is not sufficient.

   If the data collected proves statistically not significant or the data is not available in the first place, the bank must use external data on the exposure indicator concerned to calculate the capital charge.
Sufficiency of EL (7)

• In Case 2-1, EI is small, i.e. EL is not sufficient because the number of transactions in the past is not large enough or for other reasons.
  – In this instance, neither PE nor LGE is significant.
  – The capital charge should be set at the larger of:

    • The required capital amount calculated with the Formula (1-2), or
    • The required capital amount based on the PE and the LGE both set at the average level of the global data.
Sufficiency of EL (8)

- The composition of the required capital based on the PE and the LGE both set at the average level of the global data:

<table>
<thead>
<tr>
<th>EI</th>
<th>PE</th>
<th>LGE</th>
<th>γ</th>
</tr>
</thead>
<tbody>
<tr>
<td>EI</td>
<td>PE(G)</td>
<td>µL(G)</td>
<td>λ* (1+A)</td>
</tr>
<tr>
<td>EI</td>
<td></td>
<td>β₁</td>
<td></td>
</tr>
</tbody>
</table>

(Suffix G denotes global data.)

- Accordingly, the capital charge is written as β₁ * EI. The general expression for the capital charge is therefore;
  - Required capital = max [λ * EL * (1+A/√n), β₁ * EI]

(5-1)
Sufficiency of EL (9)

- In Case 2-2, on the other hand, EI is large, i.e. the observed EL is not sufficient because PE is low although the number of transactions is reasonably large.
  - In this instance, LGE is not significant. PE, which is close to zero, is not significant either.
  - The capital charge should be set at the larger of:
    - The required capital amount calculated with the Formula (1-2), or
    - The required capital amount based on the floor PE, i.e. the fixed minimum PE, and the LGE set at the average level of the global data.
Sufficiency of EL (10)

- The composition of the required capital amount based on the floor PE, i.e. the fixed minimum PE, and the LGE set at the average level of the global data:

<table>
<thead>
<tr>
<th>EI</th>
<th>PE</th>
<th>LGE</th>
<th>γ</th>
</tr>
</thead>
<tbody>
<tr>
<td>EI</td>
<td>Floor $\text{PE}_{(G)}$</td>
<td>$\mu_{L(G)}$</td>
<td>$\lambda \ast (1+A)$</td>
</tr>
<tr>
<td>EI</td>
<td></td>
<td>$\beta_2$</td>
<td></td>
</tr>
</tbody>
</table>

- Accordingly, the capital charge is written as $\beta_2 \ast EI$. The general expression for the capital charge is therefore;

  - Required capital = $\max \left[ \lambda \ast EL \ast (1+A/\sqrt{n}), \beta_2 \ast EI \right]$ (5-2)
Sufficiency of EL (11)

• $\beta_1 \times EI$ and $\beta_2 \times EI$ can be interpreted in relation to the Standardised Approach under which EI is multiplied by certain factors.

• For the purpose of further simplification, formulae (5-1) and (5-2) can be combined by using a certain $\beta'$.
  – Required capital = max [$\lambda \times EI \times (1+A/\sqrt{n})$, $\beta' \times GI$]
  – In this formula, GI, the indicator under the Standardised Approach, is selected as EI.
  – When $\beta' = f \times \beta$ is assumed ($\beta$ is the multiplication factor in the Standardised Approach), $f$ can be regarded as the floor for the IMA (in relation to the Standardised Approach).
Sufficiency of EL (12)

**Illustration**

- Required Capital
- $\beta' = f \beta$
- $\beta' \times EI$
- IMA
- Standardised Approach
- EL

\[ \text{Required Capital} \uparrow \]

\[ \beta \times EI \]

\[ \beta' = f \beta \]

\[ \beta' \times EI \]

\[ \text{IMA} \Rightarrow \text{Standardised Approach} \Rightarrow \text{EL} \]
Stability of EL (1)

• The IMA formula (1-2) is based on the EL.
  – It should be ensured that in actual application the observed EL does not fluctuate from year to year.
  – However, when a loss is experienced, which is extremely large compared to the EL observed in the past, the EL will increase substantially, hence fluctuation of the required capital amount.
Stability of EL (2)

- Mean is vulnerable to extreme values. The method for calculating the average EL should therefore be robust or resistant enough to limit the influence from such extreme cases. An example of easy solution is “trimmed mean”.
- “Trimmed mean” is a method for calculating a mean based on the data consisting only of the data points within a $[1 – 2\alpha] \%$ range around the centre of the distribution. There are the following variations.
  - “Metric Trimming”: Influence of extreme values is removed by setting them at zero.
  - “(Metric) Winsorising”: All the extreme values are replaced with data points at $[\alpha] \%$ or $[1 – \alpha] \%$.
